Field of the Invention The present invention relates to a composite photoconductive material to be used for an electrophotographic photoreceptor, an image forming method and apparatus using the same. 2. Description of the Prior Art A photoconductor is generally used for an electrophotographic photoreceptor in the field of image formation, and the electrophotographic photoreceptor includes a photosensitive layer including a photoconductive material on a conductive substrate. As the

---

photoconductive material for forming the photosensitive layer, an inorganic photoconductive material such as Se, ZnO or amorphous silicon (hereinafter referred to as a-Si) or an organic photoconductive material such as poly-N-vinylcarbazole (hereinafter referred to as P-Vc) or trinitrofluorenone polymers (hereinafter referred to as TNF) is used. Of these materials, the inorganic photoconductive material is poor in adaptability to a process for manufacturing the photoreceptor, and the organic photoconductive material is low in sensitivity and only a limited number of materials can be synthesized so that the organic photoconductive material is limited in scope of application. Recently, it has been proposed to use a technique of forming a layer including an organic semiconductor material (hereinafter referred to as an organic layer) between the conductive substrate and the photosensitive layer. For example, U.S. Pat. Nos. 4,276,364 and 4,335,166 propose a technique of forming a layer including an organic semiconductor material between a conductive substrate and a photosensitive layer. As a typical organic semiconductor material, there are an oligomer or a polymer type and an all solid type. The oligomer type includes, for example, phthalocyanine, perylene, pyrylium salt, squarylium salt, azo pigment, etc. The polymer type includes, for example, poly-N-vinylcarbazole, poly-3-alkylthiophene, etc. The all solid type includes, for example, a chalcogenide compound such as As-Te.
